1. Information about the document

These assembly instructions are intended for planners, developers and operators of systems who plan for and install linear ballscrews as machine elements. They are also intended for persons who perform the following tasks:

- Transportation
- Assembly
- Retrofitting or upgrading
- Setup
- Commissioning
- Operation
- Cleaning
- Maintenance
- Troubleshooting and error elimination

1.1 Applicability of these assembly instructions

These assembly instructions apply to all rolled, peeled and ground ballscrews from HIWIN.

1.2 Depictions used in these assembly instructions

1.2.1 Instructions

Instructions are indicated by triangular bullet points in the order in which they are to be carried out. Results of the actions carried out are indicated by ticks.

Example:

- ▶ Attach the fixed bearing firmly with bolts.
 - ▶ Tighten the bolts for the nut.
 - ▶ Move the application as close as possible to the supported bearing.
 - ▶ Attach the supported bearing firmly with bolts.
- ✓ The ballscrew with the bearing units has been mounted.

1.2.2 Lists

Lists are indicated by bullet points.

Example:

- ...
- Double nuts and preloaded single nuts must not be removed.
- Never remove recirculations.
- ...

1.2.3 Depiction of safety notices

Safety notices are always indicated using a signal word and sometimes also a symbol for the specific risk. In these instructions, the following signal words and risk levels are used:

 DANGER!
Imminent danger! Non-compliance with the safety notices will result in serious injury or death!
 WARNING!
Potentially dangerous situation! Non-compliance with the safety notices runs the risk of serious injury or death!
 CAUTION!
Potentially dangerous situation! Non-compliance with the safety notices runs the risk of slight to moderate injury!
ATTENTION!
Potentially dangerous situation! Non-compliance with the safety notices runs the risk of damage to property or environmental pollution!

1.2.4 Symbols used

The following symbols are used in these assembly instructions:

Table 1.1 Warning signs

	Warning of dangerous electrical voltage!		Warning! Danger of crushing!
	Warning of danger from suspended loads!		Substance hazardous to the environment!

1.2.5 Information

NOTE

Describes general information and recommendations.

2. Safety

WARNING!

This chapter serves to ensure the safety of everyone working with ballscrews and those who assemble, install, operate, maintain or disassemble them. Non-compliance with the following information results in dangerous working conditions.

2.1 Intended use

The ballscrew is a linear drive element, which converts a rotary movement into a lengthwise movement or vice versa and is used for the precise positioning in terms of time and location of fixed mounted loads, e.g. system components, within an automated system.

WARNING!

Danger of serious or fatal injuries!

In vertical or sloping installation positions, components may break and loads may fall.

- ▶ In the case of vertical assembly, provide a suitable clamping or braking device!

The ballscrews are designed for installation and operation in horizontal and vertical positions. **In the case of vertical or sloping assembly, a suitable clamping or braking device must be provided in order to prevent unintended lowering of the load.** Ballscrews can only be loaded in an axial direction. Radial loads result in uneven loading and may cause the ballscrew to fail prematurely.

Ballscrews may only be used for the intended purpose as described.

2.2 Exclusion of liability in the event of alterations and improper use

No alterations may be made to the ballscrews that are not described in these assembly instructions. If it is necessary to alter the design, please contact the manufacturer.

In the event of alterations or improper assembly, installation, commissioning, operation, maintenance or repair, the manufacturer shall assume no liability.

Only original parts from HIWIN may be used as spare parts and accessories. Spare parts and accessories not supplied by HIWIN are not checked for operation with HIWIN ballscrews and may restrict operational safety. The manufacturer shall accept no liability for damage caused as a result of using non-approved spare parts and accessories.

2.3 Qualified trained staff

The ballscrew may only be assembled, integrated into higher-level systems, commissioned, operated and maintained by qualified personnel. Qualified personnel are those who:

- have received appropriate technical training
and
- have received training from the machine operator concerning machine operation and the applicable safety guidelines,
and can assess the risks to be expected
and
- have read and understood these assembly instructions in their entirety and have access to them at all times.

2.4 General safety information

DANGER!

Danger from electrical voltage!

Before and during assembly, disassembly and repair work, dangerous currents may flow.

- ▶ Work may only be carried out by a qualified electrician and with the power supply disconnected!
- ▶ Before working, disconnect the higher-level system from the power supply, and secure it against restarting!

WARNING!

Danger of injury!

- ▶ During assembly and disassembly, the ballscrew must be transported horizontally. If this is not possible, a suitable holding device must be installed to prevent the ballscrew nut from coming off the ballscrew shaft!
- ▶ For long ballscrews, a hoist may be used for assembly!

2.5 Safety notices regarding storing the ballscrews

Always store ball screws in their transport packaging with protection from impact. The storage room must be dry, frost-free and free from corrosive atmosphere. Clean and protect used ball screws before storing them.

Ambient conditions

Ambient temperature +5 °C to +40 °C

Installation site flat, dry, vibration-free

Atmosphere not corrosive, not explosive

2.6 Safety notices regarding transporting the ballscrews

WARNING!

Danger from suspended loads or falling parts!

Lifting heavy loads may damage your health!

- ▶ Only qualified personnel may assemble, install, and service the ballscrews!
- ▶ Note the mass when transporting the parts. Use suitable hoisting gear!
- ▶ Observe the applicable occupational health and safety regulations when handling suspended loads!

CAUTION!

Danger of impacts and crushing!!

If no transportation safety device is used, the nut can move uncontrolled on the spindle and cause injuries.

- ▶ Only remove transportation safety device upon assembly!

ATTENTION!

Damage caused by tilting or falling!

If no transportation safety device is used, the ballscrew may tilt or fall over.

- ▶ Before transport, secure the ballscrew against tilting!

ATTENTION!

Risk of material damage!

Deflection during transport impairs the function and accuracy of the ballscrew.

- ▶ Support long ballscrews during transport at several points!

2.7 Additional information

If you have any questions, please contact our sales organisation:

Phone: +49 (0) 781 / 9 32 78-0

Fax: +49 (0) 781 / 9 32 78-90

If you have questions, suggestions or corrections concerning the documentation, please send a fax to the following number:

3. Product descriptions

3.1 Design and function of the ballscrew

The ballscrew essentially consists of the ballscrew shaft, ballscrew nut and the balls located between the shaft and nut. The balls in the ballscrew nut run around the shaft in a closed circuit and thereby convert the rotary motion of the ballscrew shaft into a linear movement of the ballscrew nut or vice versa.

3.2 Ballscrew shafts

HIWIN offers rolled, peeled and ground ballscrews – depending on the application requirements. For the selection of the appropriate shaft the individual characteristics are listed in [Table 3.1](#).

Table 3.1 Procedure for the selection of a ballscrew

	Rolled	Peeled	Ground
Profile			
Manufacturing process	Forming process	Cutting process	Grinding process
Typical applications	Transportation	Transport and positioning	Positioning
Tolerance classes	T5 – T10	T5 + T7	T0 – T5
Nominal diameter [mm]	8 – 63	16 – 80	6 – 100
Max. shaft length¹⁾ [mm]	500 – 5,600	3,300 – 6,500	110 – 10,000
Nut shapes	Flange nut Cylindrical nut	Flange nut Cylindrical nut Double nut	Flange nut Cylindrical nut Double nut
Availability	From stock	From stock	Upon request

¹⁾ Depends on the diameter and the tolerance class

3.3 Ball recirculation systems

HIWIN ballscrews are available with three different recirculation systems.

The external recirculation system consists of the ball return tube and the clamping plate. The balls are placed in the ball track between the ballscrew shaft and nut. At the end of the nut, they are guided out of the ball track and back to the start via a return tube; ball circulation is therefore a closed circuit. Because the return line is outside the nut body, this type of return is known as an external recirculation system (see [Fig. 3.1](#)).

Fig. 3.1 External recirculation type nut with return tubes

An internal separate return is fitted with deflecting parts that return the balls to the start of their thread turn. The balls undertake just one circuit around the shaft. The circuit is closed by a deflecting part in the ballscrew nut and allows the balls to return to the start via the rear of the thread. The position of the ball deflection in the nut gives the internal single recirculation system its name (see [Fig. 3.2](#)).

Fig. 3.2 **Internal single recirculation type nut with return caps**

The third type of return is the endcap recirculation system shown in Fig. 3.3. It has the same basic principle as the external return, however, the balls are returned via a channel in the ballscrew nut. The balls perform one complete cycle in the ballscrew nut. The endcap recirculation system is also called „internal total recirculation“.

Fig. 3.3 **Endcap recirculation type nut with recirculation system**

3.4 Wiper variants

NBR wiper (N): the all-rounder

The nitrile rubber wiper offers excellent sealing and wiping properties for most environmental conditions and is therefore used in almost all applications.

NBR-finger wiper (K): the one for the rough stuff

Wherever stubborn dirt prevails, it really cleans up. The finger wiper with its hard plastic fingers should not be missing in environments with coarse dirt particles.

Felt wiper (F): the most absorbent among the wipers

Felt has the property of absorbing liquids, storing them and releasing them again. This gives the felt wiper an ideal wiping effect and provides additional lubrication.

Felt-finger wiper (V): the duo

With our duo, consisting of a felt wiper and a finger wiper, dirt – whether coarse or fine – has no chance.

Table 3.2 **Wiper properties**

	NBR (N)	Felt (F)	NBR-finger (K)	Felt-finger (F)
Temperature resistance		++		+
Soiling	+		++	+
Friction reduction	++		+	
Tightness	++		++	
Emergency running		++		++
Chemical resistance	++	+	+	+

4. Assembly

⚠ DANGER!

Danger from electrical voltage!

Before and during assembly, disassembly and repair work, dangerous currents may flow.

- ▶ Work may only be carried out by a qualified electrician and with the power supply disconnected!
- ▶ Before working, disconnect the higher-level system from the power supply, and secure it against restarting!

⚠ WARNING!

Danger from suspended loads or falling parts!

Lifting heavy loads may damage your health!

- ▶ Only qualified personnel may assemble, install, and service the ballscrews!
- ▶ Note the mass when transporting the parts. Use suitable hoisting gear!
- ▶ Observe the applicable occupational health and safety regulations when handling suspended loads!

4.1 Assembling the ballscrew

⚠ WARNING!

Danger of serious or fatal injuries!

In vertical or sloping installation positions, components may break and loads may fall.

- ▶ In the case of vertical assembly, provide a suitable clamping or braking device!

Ballscrews are delivered either fully assembled or with ballscrew nuts and shafts supplied separately. In order to avoid damaging the ballscrew, the following procedures must be adhered to.

- ▶ Only remove transport packaging directly before assembly.
- ▶ Only remove the transportation safety device from the nut after the ballscrew is assembled. If this isn't possible, ensure that the ballscrew nut does not run under from the ballscrew shaft. Even if the ballscrew nut only runs off the ballscrew shaft's thread at some points, there is a risk of balls coming out of the ballscrew nut and the function no longer being guaranteed.
- ▶ Ballscrews must be installed such that there are no radial or eccentric forces acting on the nut or shaft (e.g. by a lack of alignment between bearing and nut). Ballscrews are only suited to the transfer of axial forces.

Fig. 4.1 When installing the ballscrew, there must not be any radial or eccentric forces acting on the nuts or shafts

Assembly

- ▶ Limit switches and stops should be provided on the machine to prevent the stroke distance from being exceeded and therefore damage to the unit. During assembly the nut must not be screwed out beyond the end of the shaft without an auxiliary device (assembly tube).
- ▶ Heavy ballscrews in particular must not be placed on the nut.
- ▶ The recirculation units visible from the outside must not be damaged. The recirculation units may only be disassembled in the factory.
- ▶ During installation, ensure that dirt does not accumulate on the ballscrew. Chippings and other contaminants can be removed using petroleum, thin oil or white spirit. Paint solvents and cold cleaning solvents damage the ballscrews and must therefore not be used.
- ▶ Ballscrews must be aligned perfectly flush with the guide.

4.2 Assembling and disassembling ballscrew nut on ballscrew shaft

4.2.1 Disassembling nut from ballscrew shaft

ATTENTION!

Risk of material damage!
If the nut is disassembled without an assembly tube, damage may result from balls being lost.

- ▶ Always use an assembly tube to hold the nut!

NOTE

HIWIN ballscrews are generally supplied with the nut fitted. Should this have to be disassembled, please proceed as follows:

- ▶ Double nuts and preloaded single nuts must not be removed.
- ▶ Never remove recirculations.
- ▶ Do not replace missing balls with new ones. All the balls in a ballscrew nut must always be replaced at the same time.
- ▶ An assembly tube is needed to hold the nut. The outer diameter of the assembly tube is 0.1 to 0.2 mm less than the core diameter of the thread. It is slightly longer than the nut.
- ▶ Place assembly tube on start of thread and unscrew nut according to thread direction towards assembly tube. The assembly tube prevents the balls from falling out of the nut. **The nut can now be pulled off the shaft with the assembly tube.**

Fig. 4.2 Removing nut from shaft using assembly tube

4.2.2 Assembling nut on ballscrew shaft

The nut is assembled in reverse order. Force must not be applied, otherwise the nut will be damaged. The nut must be fully on the thread before the assembly tube is removed. Then move the nut onto the shaft by a distance of at least three times the nut length.

Only assemble the ballscrew nut with a suitable assembly tube. Inappropriate auxiliary devices may result in the entire ballscrew being damaged or destroyed. Unassembled ballscrew nuts are usually supplied on an assembly tube, which can be used for correct assembly. If a special assembly tube is needed, the outer diameter of this tube should be 0.1 – 0.2 mm smaller than the core diameter of the ballscrew. The assembly tube should be around 20 mm longer than the nut.

Assembling nuts with NBR or TPU wiper

Nuts with a NBR/TPU wiper have a sealing lip which has a sliding sealing effect. The wiper therefore very reliably prevents foreign objects from entering the nut and extends its life as a result. The sealing lip also greatly reduces the amount of lubricant which can escape via the thread groove.

The nut must be assembled correctly for the sealing lip to function properly. The following points should be observed otherwise the function of the sealing lip may be impaired.

Incorrect assembly may result in the ballscrew failing prematurely.

NOTE

- ▶ The ballscrew shaft's thread should be bevelled, free of burrs and clean. Placing a small quantity of grease at the start of the thread or on the wiper makes assembly easier, protects the sealing lip and prevents damage.

Fig. 4.3 End of shaft before the NBR wiper is assembled

- ▶ Before assembly check that the two wipers are seated correctly in the nut. The wipers are aligned using a nose in the nut and must not protrude beyond the nut housing.

Fig. 4.4 Before assembly ensure that wipers are seated correctly

Assembly

- ▶ Place assembly tube on face end of ballscrew shaft. This makes it easier for the nut to be aligned with the shaft. During assembly, the nut must be aligned concentrically and flush with the shaft.

Fig. 4.5 Nut – shaft alignment

- ▶ Slide nut to start of thread and screw onto ballscrew shaft with a little pressure and a rotating movement. The wiper is then in the correct position in the thread groove. It must be possible for the nut to be screwed onto the shaft with little effort. Screw nut up to end of shaft.
If the torque needed is considerably greater or if the nut jams, unscrew it and repeat the process.

Fig. 4.6 Screw nut with wiper onto shaft

- ▶ Slowly screw nut further onto shaft and use your finger or a suitable blunt tool to fix the wiper near the sealing lip (e.g. piping of a suitable diameter). This ensures that the sealing lip runs into the thread groove correctly.

NOTE

Do not use tools with points or sharp edges otherwise there is a risk of damaging the sealing lip.

Fig. 4.7 Fixing the wiper while slowly screwing nut onto shaft

- ▶ Screw nut all the way onto the shaft and move it back and forth at least 3 nut lengths. The nut must turn easily on the shaft. Check that both wipers are seated correctly.
- ▶ Before starting up, lubricate the ballscrew as described in the lubrication instructions.

4.2.3 Replacing the wiper

ATTENTION!

Risk of material damage!

Incorrect installation may result in damage to the wipers.

- ▶ Spindle ends must always be chamfered, burr-free and clean!
- ▶ Do not use pointed tools to mount the wiper!

The wiper replacement is only intended for nuts which have a letter in the order code after the designation of the nut type, e.g. R20-05K4-DEB **(N)**1000-1200-0.023.

NOTE

HIWIN ballscrews are supplied with mounted wipers as standard. If disassembly is still necessary, please proceed as described below.

NOTE

4.2.3.1 Disassembly/assembly of the NBR/felt wiper

In case of maintenance or when replacing the NBR wiper with a felt wiper, the existing wiper must be removed. To do this, follow the steps below.

- ▶ Move the nut to the end of the shaft to make it easier to remove the circlip [4].

Fig. 4.8 Nut at the end of the shaft

- ▶ Remove the circlip [4] with a circlip pliers.

Fig. 4.9 Removing the circlip

Assembly

- ▶ Remove the metal ring [3] to expose the wiper [2].

Fig. 4.10 Removing the metal ring

- ▶ Disassemble the nut as described in Section 4.2.1 to facilitate wiper replacement. Always use a suitable assembly tube for this purpose.

Fig. 4.11 Disassembly of the nut using an assembly tube

- ▶ Remove the wiper [2] from the nut. Make sure that the inner support ring [1] remains in the nut.

Fig. 4.12 NBR wiper [2] and support ring [1]

- ▶ Place the new wiper in the nut housing and assemble the nut in reverse order.

Fig. 4.13 Nut with inserted felt wiper

- ▶ Finally mount the nut on the shaft as described in Section 4.2.2.
- ✓ The felt wiper has now been mounted.

4.2.3.2 Disassembly/assembly of the finger wiper

For nuts with optional finger wiper [6], this must first be removed in order to be able to replace the NBR or felt wiper [2]. Carry out the steps described below.

- Loosen the grub screws that fix the finger wiper [6] in the wiper housing [5].

Fig. 4.14 Loosening the grub screws

- Twist the finger wiper [6] off the spindle.

Fig. 4.15 Removing the finger wiper

Assembly

- ▶ Remove the screws securing the wiper housing [5] to the nut, and then remove the wiper housing from the nut.

Fig. 4.16 Unscrewing the wiper housing

- ✓ The finger wiper has now been disassembled
- ▶ Disassemble the NBR/felt wiper [2] as described in Section 4.2.3.1.
- ▶ Then mount the finger wiper [6] in reverse order. Note that the finger wiper can only be mounted after the nut with the mounted wiper housing has been refitted on the shaft.
- ✓ The finger wiper has now been mounted

4.2.4 Tolerance details and measuring methods for HIWIN ballscrews

Table 4.1 Radial runout t_5 of ballscrew shaft outer diameter related to AA' per length l_5 (measurement in accordance with DIN ISO 3408)

4.3 Assembly of the bearing units

4.3.1 Requirements on the mounting surface

- Adequately stable and rigid
- Evenness $\leq 0,06$ mm
- Parallelism to the guiding system ≤ 0.06 mm
- Clean

4.3.2 Cleanliness requirements

Contamination may cause damage to the rolling bearing. Cleaning residue may contribute to contamination!

Measures for safeguarding cleanliness:

- ▶ Make sure the assembly workspace is clean.
- ▶ Clean the underlying surface.

NOTE

Use only volatile solvents and lint free cloths for cleaning!

NOTE

Do not remove the bearing unit from the packaging until immediately prior to installation. The corrosion inhibitor on these components need not be removed.

4.3.3 Mounting the bearing unit

NOTE

The separate components of the bearing units have been matched to each other and may not be removed: the bearings may otherwise suffer damage.

NOTE

When mounting the bearing units, make sure that sharp edges cannot damage the seals.

NOTE

The nominal tightening torques can be taken from the bearings' data sheets.

- ▶ Install the ballscrew nut on the application, at the same time tightening the bolts only slightly.
- ▶ Using the circlip, secure the supported bearing to the ballscrew spindle (see Fig. 4.17).
- ▶ Using the locknut, secure the fixed bearing to the spindle's fixed bearing side, first tightening the locknut with double the nominal torque and then loosening the locknut after 10 min. Now tighten the locknut with the nominal torque.

Fig. 4.17 Exploded view of the ballscrew with bearing units

NOTE

The application moving over the linear guideway is used to align the bearing units.

- ▶ Move the application as close as possible to the fixed bearing (see Fig. 4.18).

Fig. 4.18 Ballscrew at the left stop for aligning the fixed bearing

The bearing unit is brought to the optimal radial position under the constraining forces exerted by the linear guideways (see Fig. 4.19).

NOTE

Fig. 4.19 Fixed bearing with applied constraining forces

- ▶ Attach the fixed bearing firmly with bolts.
- ▶ Tighten the bolts for the nut.
- ▶ Move the application as close as possible to the supported bearing.
- ▶ Attach the supported bearing firmly with bolts.

It is recommended to lock all bolts.

NOTE

The locknut must be secured with the grub screw to prevent it coming loose.

NOTE

The application should now allow movement over the full stroke under a constant force.

- ✓ The ballscrew with the bearing units has been mounted.

4.4 Mounting the separate bearings

4.4.1 Requirements on the mounting surface

- Adequately stable and rigid
- Observe the specified circularity of the bearing seat (IT 5)
- Unpainted
- Clean

4.4.2 Cleanliness requirements

Contamination may cause damage to the rolling bearing. Cleaning residue may contribute to contamination!

Measures for safeguarding cleanliness:

- Make sure the assembly workspace is clean
- Clean the bearing seat

NOTE

Use only volatile solvents and lint free cloths for cleaning!

NOTE

Do not remove the bearing unit from the packaging until immediately prior to installation. The corrosion inhibitor on these components need not be removed.

4.4.3 Mounting the bearing

NOTE

Bear in mind when mounting the bearing that the pressing force acts only on the ring that is to be pressed in. No mounting forces may be transferred through the balls.

NOTE

In the case of tighter fits, the bearing should preferably be heated for easier pressing.

NOTE

The nominal tightening torque can be taken from the bearings' data sheet.

- ▶ Using the locknut, secure the fixed bearing to the shaft's fixed bearing side, first tightening the locknut with double the nominal torque and then loosening the locknut after 10 min. Now tighten the locknut with the nominal torque.
- ▶ The bearing must lie over its whole surface on the plane face.
- ▶ Use support rings or clamps to lock the fixed bearing against loosening.
- ▶ Use circlips to lock the supported bearing against loosening.

✓ The bearing has been mounted.

4.4.4 Mounting the flange bearing

- ▶ Using the locknut, secure the flange bearing to the shaft's fixed bearing side, first tightening the locknut with double the nominal torque and then loosening the locknut after 10 min. Now tighten the locknut with the nominal torque.
- ▶ Press the fixed bearing into the bearing seat. Bolt the flange ring to the bearing seat, tightening the bolts only slightly. Adjustments can then still be made to the radial position.
- ▶ After aligning the shaft, tighten the screws proceeding in a crosswise fashion.

✓ The bearing has been mounted.

5. Maintenance

DANGER!

Danger from electrical voltage!

Before and during assembly, disassembly and repair work, dangerous currents may flow.

- ▶ Work may only be carried out by a qualified electrician and with the power supply disconnected!
- ▶ Before working, disconnect the higher-level system from the power supply, and secure it against restarting!

5.1 Cleaning

ATTENTION!

Damage to the ballscrew due to improper cleaning!

- ▶ The legal regulations and the manufacturer's regulations concerning the use of cleaning agents must be observed!
- ▶ Damage of the ballscrew by pointed objects must be avoided!
- ▶ When cleaning, make sure that no metal particles end up or remain in the ball track or ballscrew nut!

- Ballscrews can be cleaned using white spirit and oil.
- Trichlorethylene or an equivalent cleaning agent can be used as a degreasing agent.
- In order to avoid corrosion, all parts must be dried and preserved/lubricated after cleaning.

6. Lubrication

6.1 General information about lubrication

Ballscrews need a sufficient supply of lubricant to ensure their function and service life.

The specifications and information provided below are intended to help the user select an appropriate lubricant, the corresponding amount of lubricant and establish the lubrication intervals.

These lubrication instructions do not mean that the user does not have to check the defined lubrication intervals in reality and correct them if necessary. After every lubrication process check whether there is sufficient lubricant on the machine element (check for a film of lubricant).

Lubricants

- reduce wear
- protect against dirt
- prevent corrosion

The lubricant is a design element and should be taken into account when designing a machine. The operating temperature range and operating and ambient conditions should be considered when selecting the lubricant.

6.1.1 Safety

ATTENTION!

Warning! Health and environmental hazards!

Contact with lubricants may cause irritation, poisoning, allergic reactions, and damage to the environment.

- ▶ Use only suitable, non-hazardous agents. Note the manufacturer's safety data sheets!
- ▶ Ensure proper disposal!

Proper use of lubricants

This chapter explains how to use lubricants safely. Improper handling of lubricants may endanger life and limb. It is essential that the following information is observed. Before handling lubricants, always note the associated safety data sheet.

- Recurring contact with the skin over long periods should be avoided wherever possible. Clean wetted areas of skin with soap and water. Use skin protection during work and a moisturising cream afterwards. Wear oil-resistant protective clothing if necessary (e.g. gloves, apron). Do not clean your hands with petroleum, solvents or coolants that can be or are mixed with water. Oil mists must be extracted from their point of origin.
- Wear safety goggles to avoid contact with the eyes. Should lubricants come into contact with the eyes, the areas affected should be rinsed with plenty of water. Seek the advice of an ophthalmologist if eyes feel irritated for long periods.
- If swallowed by mistake, do not induce vomiting. Call the doctor immediately.
- Safety data sheets in accordance with 91/155/EEC are generally available for lubricants. These contain detailed information about protecting your health and the environment and preventing accidents.
- Lubricants are generally a risk to waterways. They must not therefore enter the ground, water or sewerage system.

6.1.2 Safety notices regarding storing lubricants

Store the lubricants in a cool and dry location in well-sealed containers. They should be protected from direct sunlight and frost. Lubricants must not be stored in the same place as foodstuffs. Lubricants must not be stored in the same place as oxidants.

6.2 Lubrication provided upon delivery

HIWIN ballscrews are supplied preserved as standard. A mineral oil-based grease for rolling and slide bearings containing thickening agents in accordance with DIN 51825 (K2K), NLGI class 2 is used to preserve the ballscrews. Viscosity of base oil: 60 mm²/s. Initial lubrication should be undertaken before starting up for the first time (see section 6.7.1.1)

6.3 Selecting the lubricant

Oils, greases or even semi-fluid grease can be used.

The lubricants that you would use for a rolling bearing can be used. The choice of lubricant and type of supply can usually be adjusted to the lubrication used for the rest of the machine components.

Lubricants containing MoS₂ or graphite must not be used.

NOTE

6.4 Miscibility

Check the miscibility of different lubricants. Mineral oil-based lubricant oils with the same classification (e.g. CL) and a similar viscosity (maximum of one class difference) can be mixed.

Greases are miscible when their base oil and thickening types are the same. The viscosity of the base oil must be similar. The NLGI class may differ by no more than one stage.

If lubricants other than those specified are used, shorter lubrication intervals and diminished performance should be expected. Potential chemical interactions between plastics, lubricants and preservatives must be expected.

Table 6.1 Miscibility of HIWIN greases

	G01	G02	G03	G04	G05
G01	●	●	●	○	○
G02	●	●	●	●	●
G03	●	●	●	●	●
G04	○	●	●	●	●
G05	○	●	●	●	●

Table 6.2 Compatibility of preserved products with HIWIN greases

	G01	G02	G03	G04	G05
Standard ballscrews	○	●	●	●	●
Heavy-duty ballscrews	●	●	●	○	○

- miscible
- partly miscible

Recommendation:

Using lubricants, which are only partially miscible, the old grease should be used up as much as possible before the new grease is introduced. The relubrication quantity of the new grease should be temporarily increased.

Using lubricants, which are immiscible, the old grease should be removed completely before the new grease is introduced.

6.5 Operating conditions

The choice of lubricant basically depends on operating temperature and various operating factors, such as level of loading, oscillations, vibrations or short-stroke applications. Special requirements, such as use in conjunction with strong or aggressive media applications, in clean rooms, in a vacuum or in the food industry are also taken into consideration.

Applications and suitable lubricants are listed in chapter 6.8. If in any doubt, contact the lubricant manufacturer to ensure optimum lubrication.

6.6 Use of greases and oils in central lubrication systems

When using a central lubrication system, it is recommended that the initial lubrication (see section 6.7.1.1) is carried out separately using a manual grease gun before connection to the system. Furthermore, make sure that all pipes and elements up to the user are filled with lubricant and that no air pockets are present.

Long pipelines and narrow pipe diameters are to be avoided. The pipes are to be installed on an incline.

The pulse count results from the partial quantities and the piston distributor sizes.

In addition, the lubrication system manufacturer's regulations must be observed.

6.7 Lubricating ballscrews

HIWIN ballscrews can be lubricated with grease, semi-fluid grease or oil depending on the application. The lubricant pressure required depends on the nominal diameter, lubricant, length of the feed pipe and the type of lubrication connection.

NOTE

Too high a lubrication pressure or too great a lubricant quantity may destroy the ballscrews.

In particular, for ballscrew nuts with felt or lip sealing, lubrication must be carried out very carefully, otherwise the seals may be damaged.

6.7.1 General information about lubricant quantities

6.7.1.1 Initial lubrication upon commissioning

HIWIN ballscrews are supplied preserved as standard. The initial lubrication takes place in three steps:

Supply the amount of grease stated for the range in the table. Move the nut three times by approx. three nut lengths. Repeat the aforementioned process twice more.

Initial lubrication for short-stroke applications:

Stroke $< 2 \times$ nut length: Provide lubricant connections on both sides of the nut and lubricate.

Stroke $< 0.5 \times$ nut length: Provide lubricant connections on both sides of the nut and lubricate. In doing so, move the ballscrew nut by two nut lengths several times. If this is not possible, please contact us.

The quantities stated in the corresponding tables should be doubled for short-stroke applications.

If nuts do not have a lubricant connection, supply via the shaft.

6.7.1.2 Relubrication

The lubrication intervals depend heavily on the operating conditions (nominal size, lead, speed, acceleration, loads, etc.) and environmental conditions (temperature, fluids etc.). Environmental influences such as high loads, vibrations and dirt shorten the lubrication intervals. For clean environmental conditions and light loads, the lubrication intervals can be extended.

If the ballscrews are fitted vertically, the relubrication quantities must be increased by roughly 50 %.

For normal operating conditions, the lubrication intervals provided shall apply.

Twice the amount of lubricant should be used for relubrication with short-stroke applications.

6.8 Lubricant recommendations

The choice of lubricant basically depends on operating temperature and various operating factors, such as level of loading, oscillations, vibrations or short-stroke applications. Special requirements, such as use in conjunction with strong or aggressive media applications, in clean rooms, in a vacuum or in the food industry are also taken into consideration.

Applications and suitable lubricants are listed below. If in any doubt, contact the lubricant manufacturer to ensure optimum lubrication.

6.8.1 Grease lubrication

For grease lubrication, we recommend mineral oil-based grease for rolling and slide bearings with thickening agents in accordance with DIN51825 (K1K, K2K). EP additives are needed for heavy-duty applications (KP1K, KP2K). NLGI class 1 or 2 and other consistency classes can be used following consultation with the lubricant manufacturer.

Greases containing solid lubricants such as graphite or MOS_2 must not be used.

NOTE

The following lubricant details are examples and should only be used to assist with selection. Other lubricants can be used once the application has been discussed with the lubricant supplier.

6.8.1.1 Standard applications

Load: max. 15 % of the dynamic load rating

Temperature range: -10 °C to $+80\text{ °C}$

Specific speed value: $< 120,000$

6.8.2 Semi-fluid grease lubrication

Semi-fluid greases are often used in central lubrication systems because their soft structure allows them to be better distributed.

Observe the information provided by the lubrication system manufacturer.

The following lubricant details are examples and should only be used to assist with selection. Other lubricants can be used once the application and central lubrication system used have been discussed with the lubricant supplier.

In addition, the lubrication system manufacturer's regulations must be observed.

Lubrication

6.8.3 Oil lubrication

The benefits of lubricating oils include more even distribution and better access to contact points. This does however mean that lubricating oils collect in the lower part of the product due to the force of gravity and get dirty more quickly. Larger amounts of oil are therefore needed than grease. Oil lubrication is usually only suited to use with central lubrication units or products fitted with a lubrication unit.

Observe the information provided by the lubrication system manufacturer.

The following lubricant details are examples and should only be used to assist with selection. Other lubricants can be selected once the application and central lubrication system used have been discussed with the lubricant supplier.

6.8.3.1 Standard applications

Load: max. 15 % of the dynamic load rating

Temperature range: -10 °C to +80 °C

6.9 Lubricant quantities and lubrication intervals

ATTENTION!

Danger of damage to the linear guideways due to missing or incorrect lubrication!

Missing initial lubrication or excessive lubricant quantities/excessive lubrication pressure can damage or destroy the product.

- ▶ Never put the linear guideway into operation without initial lubrication!
- ▶ The specified procedure must be observed in order to avoid damaging the product!

The lubricant quantities specified below are reference values that may fluctuate according to the environmental conditions.

6.9.1 Lubricant quantities and lubrication intervals for grease lubrication

Lubrication

Relubrication interval for grease lubrication

The relubrication intervals for grease lubrication under standard conditions are between 200 and 600 hours of operation or 100 km in a clean environment (reference values).

Standard conditions:

Load ratio: max. 20 % of the dynamic load rating

Temperature range: -10 °C to + 80 °C

Specific speed value: < 120,000

No impacts or vibrations

Deviating conditions and dirt reduce the relubrication intervals.

6.9.2 Lubricant quantities and lubrication intervals for semi-fluid grease lubrication

When using a central lubrication system, it is recommended that the initial lubrication is carried out separately using a manual grease gun before connection to the system.

Furthermore, make sure that all pipes and elements up to the user are filled with lubricant and that no air pockets are present. Long pipelines and narrow pipe diameters are to be avoided. The pipes are to be installed on an incline. The pulse count results from the partial quantities and the piston distributor sizes.

In addition, the lubrication system manufacturer's regulations must be observed.

Lubricant quantities for semi-fluid grease lubrication:

The quantities for lubrication with semi-fluid grease are identical to those for grease lubrication.

Relubrication interval for semi-fluid grease lubrication:

The relubrication intervals for semi-fluid grease lubrication are reduced to 50 % of the relubrication intervals for grease lubrication (period between two lubrications).

Piston distributor sizes for feed units (single-line systems) for semi-fluid grease lubrication

The interval between the individual lubrication pulses results from the relubrication quantity, the relubrication interval and the piston distributor size:

$$\text{Interval between lubrication pulses [km]} = \frac{\text{Piston distributor size [cm}^3\text{]}}{\text{Relubrication quantity [cm}^3\text{]}} \times \text{Relubrication interval [km]}$$

6.9.3 Lubricant quantities and lubrication intervals for oil lubrication

When using a central lubrication system, make sure that all pipes and elements up to the user are filled with lubricant and that no air pockets are present. Long pipelines and narrow pipe diameters are to be avoided. The pipes are to be installed on an incline.

The pulse count results from the partial quantities and the piston distributor sizes.

In addition, the lubrication system manufacturer's regulations must be observed.

Table 6.21 Lubricant quantities for oil lubrication

Nominal diameter [mm]	Initial lubrication	Relubrication
	Partial oil quantity [cm ³]	Oil quantity [cm ³]
8	0.2 (3 ×)	0.1
10	0.2 (3 ×)	0.1
12	0.2 (3 ×)	0.1
16	0.3 (3 ×)	0.2
20	0.3 (3 ×)	0.3
25	0.5 (3 ×)	0.5
32	0.5 (3 ×)	0.5
40	0.9 (3 ×)	0.7
50	1.1 (3 ×)	1.0
63	2.0 (3 ×)	1.5
80	3.0 (3 ×)	2.0

Oil bath lubrication:

If using oil bath lubrication, the shaft should be 0.5 to 1 mm above the oil level.

Relubrication interval for oil lubrication:

The relubrication intervals for oil lubrication should not exceed 8 hours with the oil quantity stated above.

Piston distributor sizes for feed units (single-line systems) for semi-fluid oil lubrication

The interval between the individual lubrication pulses results from the relubrication quantity, the relubrication interval and the piston distributor size:

$$\text{Interval between lubrication pulses [km]} = \frac{\text{Piston distributor size [cm}^3\text{]}}{\text{Relubrication quantity [cm}^3\text{]}} \times \text{Relubrication interval [km]}$$

7. Incident procedures

7.1 Troubleshooting and error elimination

This chapter explains potential ballscrew malfunctions and how to avoid them. It also introduces several measuring devices which allow the user to localise the causes of excess clearance.

7.2 Causes of errors and error prevention

The main sources of error can be split into four categories:

7.2.1 Excess play

No preload or insufficient preload:

If the ballscrew is held vertically and the nut can be pulled down under its own weight and rotated around the shaft, the ballscrew has play or is slightly preloaded. Ballscrews without preload may have significant axial backlash; they are therefore used in applications which do not primarily require high accuracy levels.

HIWIN establishes the preload needed for the application and supplies the ballscrew with the necessary preload. A detailed and accurate description of the usage conditions is therefore very important for HIWIN ballscrew orders.

Fig. 7.1 Structure of a ballscrew

The following measurements can be taken to establish the reason behind abnormal play in the ballscrew:

1. Glue ball gauge in central hole at one end of ballscrew shaft. Use a dial gauge to measure the axial backlash of the ball gauge as you rotate the ballscrew shaft. [Fig. 7.2 (a)]. It should not move any more than 0.003 mm if the bearing, ballscrew nut and nut housing are fitted correctly.
2. Use a dial gauge to measure the relative movement between the bearing housing and bearing seat as you rotate the ballscrew shaft [Fig. 7.2 (b)]. Any measurement other than zero shows that the bearing is either not rigid enough or incorrectly mounted.
3. Check relative movement between machine bed and housing of ballscrew nut [Fig. 7.2 (c)].
4. Check relative movement between housing of ballscrew nut and flange [Fig. 7.2 (d)].

Contact HIWIN if the tests described do not yield anything but play is still present. The preload or rigidity of the ballscrew may have to be increased.

Fig. 7.2 Establishing reason for abnormal play

7.2.2 Excess torsional deformation

1. Incorrect choice of material:

Table 7.1 is an overview of the materials to be used in ballscrews for shafts and nuts.

Table 7.1 **Material**

	Material numbers according to DIN EN 10027		
Component	Rolled ballscrews	Peeled ballscrews	Ground ballscrews
Shaft	1.1213	1.1213 1.7225	1.7228
Nut ¹⁾		1.6523 ¹⁾	
Ball		1.3505	

¹⁾ Special nuts 16MnCr5B

2. Incorrect heat treatment:

Depth of heat-treated layer too shallow, uneven surface heat treatment, material too soft: The standard hardnesses for balls, nuts and shafts are listed in Table 7.2.

Table 7.2 **Standard hardnesses**

	Hardness
Shaft	58 – 62 HRC
Nut	58 – 62 HRC
Ball	62 – 66 HRC

3. Design errors, ratio of length to diameter too large etc.:

The smaller the ratio of shaft length to diameter (L/D figure), the greater the rigidity. The recommended L/D figure is less than 60. Too high an L/D figure may result in significant torsional deformation. Wherever possible, assembly with bearings on one side should be avoided.

4. Incorrect choice of bearings:

Ballscrews should be mounted with angular ball bearings; angular ball bearings designed especially for ballscrews are recommended in particular. When axial loads occur, normal ball bearings display considerable axial backlash; such bearings should not therefore be used for applications with axial loads.

5. Nut housing or bearing housing is not rigid enough

The housing mounted on the ballscrew nut or on a bearing may twist under the weight of the components or machine load if not rigid enough. The test structure shown in Fig. 7.2 (d) can be used to test the rigidity of the nut housing. Similar test structures can be used to test the rigidity of bearing housings.

6. Nut housing or bearing housing is not mounted correctly

- Vibration or a lack of dowel pins may cause the components to come loose. Fixed dowel pins and not clamping pins should be used to lock.
- The screw connection on the ballscrew nut is not secure because the screws are too long and/or the threaded holes on the housing are too short.
- Vibration and a lack of circlips causes the screws on the ballscrew nut to come loose.

7. Housing surface is not parallel or flat enough

When the machine is assembled, spacers are often fitted between the housing and machine frame for adjustment. The dimensions of the mounting surface may vary at different points if the surface parallelism or evenness of the components is not within tolerance.

Incident procedures

8. Motor and ballscrew are not fitted correctly

- If the coupling is not fitted securely or is not rigid enough, relative rotation results between the motor shaft and ballscrew shaft.
- Gear teeth do not mesh correctly or the driveline is not rigid enough. If the ballscrew is driven by a belt, a toothed belt should be used to avoid slipping.
- Feather key is loose in groove. Any incorrect combination of shaft, groove and feather key may cause play.

7.2.3 Uneven running

1. Production-related defects on ballscrew

- The race profile on the ballscrew shaft or nut is too rough.
- The bearing balls, ballscrew nut or shaft are out of round.
- The lead or lead circle diameter of ballscrew nut or shaft are outside tolerance.
- The ball return is not correctly fitted in the ballscrew nut.
- Uneven ball size or hardness.
These problems should not arise with high-quality manufacturers.

2. Foreign objects in ball race profile

- Packaging material jammed in ball race profile. Before being shipped, ballscrews are packaged with various packaging materials and oil paper. These materials and other objects may jam in the ball race profile if care is not exercised when assembling and aligning the ballscrew. This may cause the balls to slide rather than roll or even jam completely.
- Machine chips enter the ball track. Chips or dust from machine operations may enter the ball track if wipers are not used to keep items away from the ballscrew's race profiles. This causes uneven running, reduced accuracy and a shortened life.

3. Operation beyond the maximum useful path

Travel beyond the maximum useful path may damage or even destroy the recirculation system. If this happens, the balls are no longer able to circulate evenly. In the worst cases, they may break and the race profile on the ballscrew shaft or nut be damaged. Operation beyond the maximum useful path may occur when setting up, as a result of limit switch failure or due to collisions in the machine. To avoid further damage, after exceeding the path, a ballscrew must be checked and repaired by the manufacturer before being used again.

4. Ball return damaged

The ball return may be damaged and cause the problems described above if it experiences severe impact during assembly.

5. Incorrect alignment

If the axles of the ballscrew nut housing and the shaft bearing don't fully match, radial load occurs. The ballscrew may bend if the load is excessive. Even if the axle error is so minor as to cause no discernible bending, it will still cause increased wear. If incorrectly aligned, the ballscrew accuracy will quickly deteriorate. The greater the ballscrew nut preload, the greater the need for the ballscrew to be accurately aligned.

6. Ballscrew nut not correctly mounted on housing

If the ballscrew nut is mounted at an angle or poorly aligned, eccentric loads occur. If this happens, the motor input current may fluctuate during operation.

7. Transport damage to ballscrew

7.2.4 Breakage

1. Broken ball

Cr-Mo steel is the material most commonly used for bearing balls. A load of 1,400 – 1,600 kg is needed to break a ball with a diameter of 3.175 mm. The temperature of a ball with insufficient or no lubrication rises continuously during operation. This increase in temperature can make the balls brittle and cause them to break, which then results in damage to the race profile in the ballscrew nut and on the shaft. The process of topping up lubricant should therefore be taken into account at the design stage. If an automatic lubrication system cannot be used, regular lubricant top-ups should be included in the maintenance schedule.

2. Pressed-in or broken ball return

If the ballscrew nuts travel beyond the permissible path or impact against the ball return, the return may be pressed in or broken. This blocks the path for the balls, so they simply slide and ultimately break.

3. Bearing journal breakage on shaft

○ Incorrect design:

Sharp edges should be avoided on the shaft's bearing journal to avoid local peaks in stress. Fig. 7.3 shows useful design features for the bearing journal.

○ Bending strain on the bearing journal:

The bearing's mounting surface and the bearing lug's axle are not perpendicular to one another or the opposite sides of the bearing lug are not parallel to one another. The bearing journal is thereby bent and may ultimately break. The deviation in the bearing journal position before and after the bearing lug is tightened should not exceed 0.01 mm.

○ Radial load or load fluctuations:

Incorrect alignment during ballscrew assembly causes abnormal fluctuating shearing loads and therefore premature ballscrew failure.

Fig. 7.3 Recesses for avoiding peaks in stress

Fig. 7.4 Concentricity check on drive journal

Incident procedures

Table 7.3 **Fault table**

Fault	Possible cause	Remedy
High level of operating noise while the ballscrew is running	Ballscrew speed too high	Check the permissible specific speed value
	Insufficient lubrication	Lubricate the ballscrew as specified in the lubrication instructions
	Ballscrew is not mounted axially parallel with the guides	Align the ballscrew
	Nut, shaft or balls displaying traces of wear	Replace the ballscrew
Ballscrew nut is sluggish near the mounting	Ballscrew is not mounted axially parallel with the guides	Align the ballscrew
Ballscrew nut is sluggish over its entire travel distance	Ballscrew nut has radial load or is not axially parallel with the shaft	Check alignment of nut housing to ballscrew mounting
	Dirt has entered the nut and is making it sluggish	Check the wipers Replace and check the ballscrew
	One or more of the ballscrew components are damaged	Replace the ballscrew
Ballscrew nut is heating up a lot	Ballscrew nut has radial load or is not axially parallel with the shaft	Check alignment of nut housing to ballscrew mounting
	Insufficient lubrication	Lubricate the ballscrew as specified in the lubrication instructions

8. Disposal

ATTENTION!

Danger caused by environmentally hazardous substances!

The danger to the environment depends on the type of substance used.

- ▶ Clean contaminated parts thoroughly before disposal!
- ▶ Clarify the requirements for safe disposal with disposal companies and, where appropriate, with the competent authorities!

Fluids

Lubricants	Dispose of as hazardous waste in an environmentally friendly way
Soiled cleaning cloths	Dispose of as hazardous waste in an environmentally friendly w

Appendix 1: Order codes

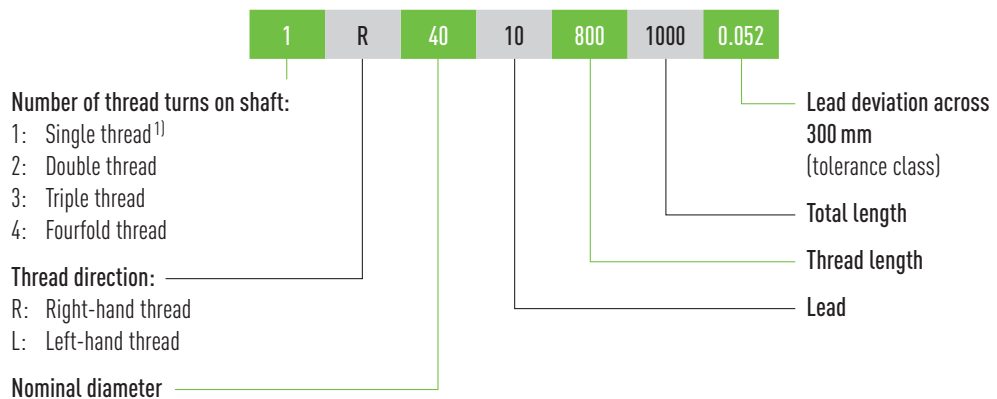

9. Appendix 1: Order codes

In order to clearly identify the ballscrew, information about the ballscrew shaft and nut is needed.

9.1 Order codes for rolled ballscrews

Order code for ballscrew shaft without the nut

Order code for ballscrew nut without the shaft

¹⁾ Standard; can be omitted with single-thread shafts

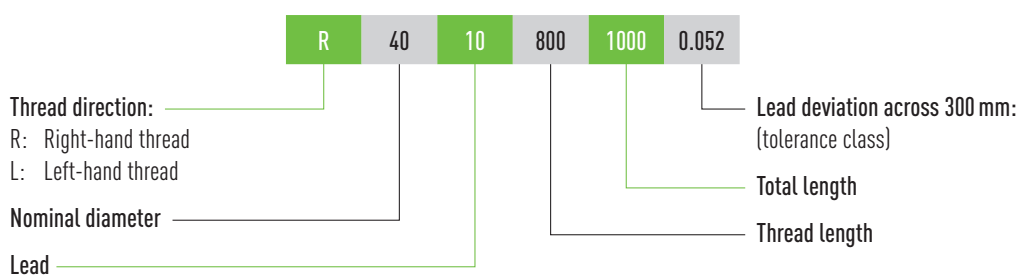

Table 9.1 Overview of nut shapes

Nut designation	Description
FSIDIN	Flange single nut with internal single recirculation
FSCDIN	Flange single nut with cassette recirculation
RSI	Cylindrical single nut with internal single return
RSIT	Cylindrical single nut with screw-in thread and internal single return

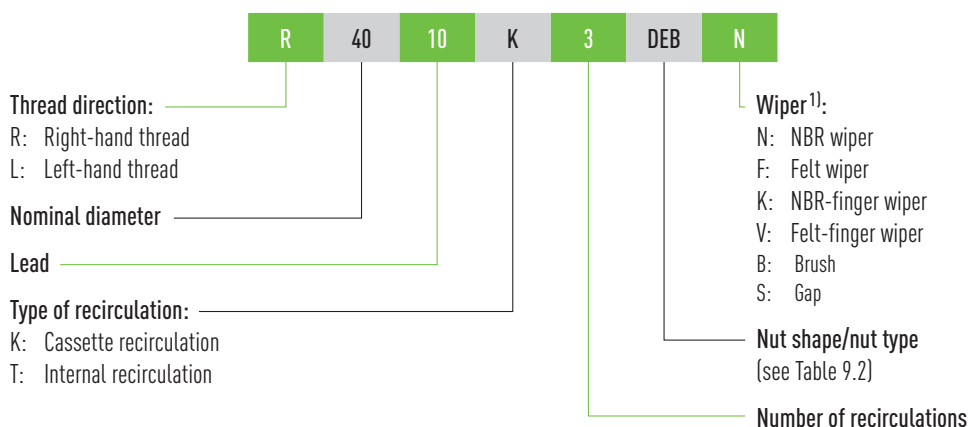

9.2 Order codes for peeled ballscrews

Order code for ballscrew shaft without the nut

Order code for ballscrew nut without the shaft

¹⁾ The wiper used is shown in the following tables for the individual nut types. For the DEB-x and DDB-x nut types, you can choose between N, K, F or V wipers, depending on the thread pitch.

Appendix 1: Order codes

Table 9.2 **Overview of nut shapes**

Nut designation	Description
DEB-x	Flange single nut with variable wiper type
DDB-x	Flange double nut with variable wiper type
ZE	Cylindrical single nut
SE	Cylindrical single nut with screw-in thread
SEM	Flange single nut with integrated locking nut ¹⁾

¹⁾ Simply using a safety nut does not provide sufficient protection against a load being lowered unintentionally. The safety guidelines valid for the application must be observed. The safety nut it is not a safety component according to the Machinery Directive.

10. Appendix 2: Product specifications and technical data

10.1 Buckling load and critical speed

10.1.1 Buckling load

F 10.1

$$F_k = 4.072 \times 10^5 \left(\frac{f_k \times d_k^4}{l_s^2} \right)$$

- F_k Permissible load [N]
- F_{kmax} Max. permissible load [N]
- d_k Core diameter of threaded shaft [mm]
- l_s Unsupported shaft length [mm]
- f_k Factor for different types of assembly (buckling load)

F 10.2

$$F_{kmax} = 0.5 \times F_k$$

- Fixed bearing – fixed bearing $f_k = 1.0$
- Fixed bearing – supported bearing $f_k = 0.5$
- Supported bearing – supported bearing $f_k = 0.25$
- Fixed bearing – no bearing $f_k = 0.0625$

Fig. 10.1 Buckling load for different diameters and lengths of threaded shafts

Appendix 2: Product specifications and technical data

10.1.2 Critical speed

F 10.3
$$n_k = 2.71 \times 10^8 \left(\frac{f_n \times d_k}{l_s^2} \right)$$

F 10.4
$$n_{kmax} = 0.8 \times n_k$$

- n_k Critical speed [rpm]
- n_{kmax} Max. permissible speed [rpm]
- d_k Core diameter of threaded shaft [mm]
- l_s Unsupported shaft length [mm]
- f_n Factor for different types of assembly (critical speed)

- Fixed bearing – fixed bearing $f_n = 1.0$
- Fixed bearing – supported bearing $f_n = 0.692$
- Supported bearing – supported bearing $f_n = 0.446$
- Fixed bearing – no bearing $f_n = 0.147$

All dimensions stated without a unit are in mm

Note:

Simply using a safety nut does not provide sufficient protection against a load being lowered unintentionally. The safety guidelines valid for the application must be observed. The safety nut it is not a safety component according to the Machinery Directive.

Appendix 2: Product specifications and technical data

10.2.3 Driven nut unit AME

Sample application

The tool carriage of a machining centre can be moved up to 3,000 mm. The maximum rapid motion speed is 25 m/min. The rotary speed of the long feed shaft required for this cannot be reached due to its considerably lower critical bending speed. The ballscrew nut is therefore driven rather than the ballscrew shaft. High axial and radial loading capacity and a good resistance to tilting are required of the bearing.

Design solution

The threaded nut is mounted in an axial angular ball bearing ZKLF...2Z. The less stringent PE version is preferred. The bearing has defined preload using a precision groove nut from the HIR series. The bearing achieves a good resistance to tilting thanks to the O arrangement of the two rows of balls. Any axial and radial forces which arise are absorbed with ease. The thick-walled, dimensionally-stable outer bearing race is screwed directly onto the bearing block.

There is no need for an extra bearing bush or bearing cover. Circulating oil lubrication supplies the bearing with lubricant. The ballscrew nut is lubricated via a radial bore in the shaft. The less stringent axial angular ball bearing can only be lubricated axially.

We are happy to develop the right unit for any application, taking due account of different installation circumstances. A wide range of realised applications provides the ideal basis for finding a solution to your problem.

10.2.6 Axial angular contact ball bearing

ZKLN series

Axial angular contact ball bearings of the ZKLN...2RS series are angular contact ball bearings in two rows with a 60° contact angle in an O arrangement. The outer race has a thick wall and is inherently stable. An accuracy of IT6 is therefore sufficient for the housing bore. The surround surface of the outer race has a lubrication groove and three lubrication holes. The two-part inner race is matched to the two ball and cage

ZKLF series

The differences between bearings of the ZKLF series and those of the ZKLN series are an outer race which can be unscrewed and a different lubrication hole arrangement. Directly screwing the outer race onto the connection construction means that the bearing cover usually needed to lock it in place is not required, neither is the adaptation

Less stringent PE version

In their normal version, the axial angular contact ball bearings ZKLN and ZKLF are designed for high-precision ballscrews. In many applications, such as handling, wood-working machines and mounting several ballscrews, this precision is not essential. A cheaper version with less stringent tolerances can often achieve the accuracy required for the function.

The ZKLN and ZKLF series with less stringent tolerances (indicated by the additional characters PE) provide the characteristics of the normal version, such as good loading capacity and rigidity with a high speed limit, as well as being easy to assemble and requiring little maintenance.

Benefits of the less stringent version:

- Cheaper
- Unit suited to function
- Less production work involved in connection construction

The less stringent PE version is available in hole diameters of 12 to 50.

Installation/removal

When installing the axial angular contact ball bearing, ensure that the assembly forces are not channelled via the rolling elements.

The mounting bolts of the ZKLF bearing should be tightened crosswise. The mounting bolts may be loaded up to 70 % of their yield strength.

The surround surface of the outer race has an extraction slot all the way round to speed up removal of bearings in the ZKLF series.

Tightening the lock nuts preloads the axial angular ball bearings. The lock nut tightening torques stated in the dimensions tables should be observed.

Once the lock nuts have been tightened, the two locking threaded pins should be tightened with a hexagon socket. Tighten the locking threaded pins alternately.

Lubrication

The bearings are greased using a lithium soap grease to GA28 and can be lubricated via the lubrication connectors in the outer ring. For the majority of applications, the initial greasing is sufficient for the whole bearing operating life.

assemblies and outer race such that the bearing is ideally preloaded when the lock nut is tightened to the specified tightening torque. Axial angular contact ball bearings are self-locking. They have sealing rings on both sides and are supplied ready to install and greased for life. No additional seals are needed in the surrounding construction.

work required in advance. There is an extraction slot all the way round the surround surface of the outer race to simplify disassembly. One radial and one axial M6 threaded hole permit re-lubrication in special applications.

Contact sealing disc
Additional characters .2RS

Gap seal
Additional characters .ZZ

To counteract settling effects, we would recommend initially tightening the lock nuts to three times the stated tightening torque M_A . Then relieve the lock nuts. They should then be tightened again to the tightening torques M_A stated in the dimensions tables.

When disassembling, proceed in reverse and first loosen the two locking threaded pins and then the lock nuts. If assembled and disassembled correctly, lock nuts can be used several times.

The dimensions of the bearing's inner races are such that a defined preload, sufficient for most applications, is achieved when the lock nut is tightened (tightening torque M_A according to dimensions table).

Deviating tightening torques M_A can be selected for special applications. Please contact us in such instances.

If the bearing friction torque M_{RL} can be checked, compare the values measured with those in the dimensions tables.

The ball cages are made from plastic, permissible operating temperature 120 °C (continuous operation)

¹⁾ Contact angle $\alpha = 60^\circ$

²⁾ Hole diameter tolerance as of d = 6 mm: D $\begin{smallmatrix} +0.002 \\ -0.003 \end{smallmatrix}$; d = 10 – 50 mm: D $\begin{smallmatrix} 0 \\ -0.005 \end{smallmatrix}$; d = 60 – 100 mm: D $\begin{smallmatrix} 0 \\ -0.008 \end{smallmatrix}$

³⁾ Outer diameter tolerance as of d = 6 – 50 mm: d $\begin{smallmatrix} 0 \\ -0.01 \end{smallmatrix}$; d = 60 – 100 mm: d $\begin{smallmatrix} 0 \\ -0.015 \end{smallmatrix}$

⁴⁾ Recommended diameter of installation surface

.2Z = Gap seal

.2RS = Contact seal
